1 STAT 207: The MM Algorithm

The MM algorithm:

- Original paper Lange, K., Hunter, D. R., & Yang, I. (2000). Optimization transfer using surrogate objective functions. Journal of computational and graphical statistics, 9(1), 1-20.
- relies on convexity arguments and is useful in high-dimensional problems such as image reconstruction.
- The first "M": majorize/minorize; the second "M": minimize/maximize depending on the problem.
- It substitutes a difficult optimization problem with a simpler one.
 - a) avoiding large matrix inversions,
 - b) linearizing the problem,
 - c) separating the variables,
 - d) dealing with equality and inequality constraints,
 - e) turning a nondifferentiable problem into a smooth problem.
- The price of simplifying the problem is iteration or iteration with slower convergence.
- The EM algorithm is a special case of the MM algorithm developed by statisticians that deals with missing data.
- Compared to other algorithms, the MM algorithm has
 - greater generality,
 - more obvious connection to convexity,
 - weaker reliance on difficult statistical principles.

1.1 Definition

A function $g(x|x_n)$ is said to **majorize** a function f(x) at x_n provided

$$f(x_n) = g(x_n|x_n),$$

$$f(x) \le g(x|x_n), \forall x \ne x_n.$$

Here x_n represents the current iterate in a search of the surface f(x).

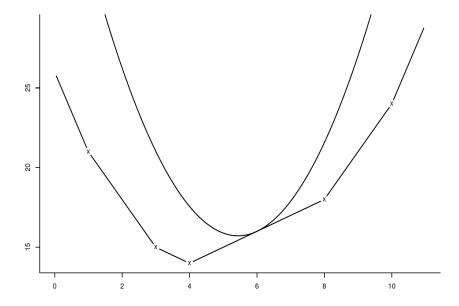

FIGURE 12.1. A Quadratic Majorizing Function for the Piecewise Linear Function f(x) = |x-1| + |x-3| + |x-4| + |x-8| + |x-10| at the Point $x_n = 6$

In the **minimization** version of the MM algorithm, we minimize the surrogate majorizing function $g(x|x_n)$ rather than the actual function f(x).

• If x_{n+1} denotes the minimum of the surrogate $g(x|x_n)$, then we can show that the MM procedure forces f(x) downhill.

$$f(x_{n+1})\leq g(x_{n+1}|x_n)\leq g(x_n|x_n)=f(x_n)$$

- The descent property lends the MM algorithm remarkable numerical stability.
- It depends only on decreasing the surrogate function $g(x|x_n)$, not on minimizing it.
- In practice, when the minimum of $g(x|x_n)$ cannot be found exactly.
- When f(x) is strictly convex, one can show with a few additional mild hypotheses that the iterates x_n converge to the global minimum of f(x) regardless of the initial point x_0 .
- x_n is a stationary point of $g(x|x_n) f(x)$, with

$$\nabla g(x_n|x_n) = \nabla f(x_n).$$

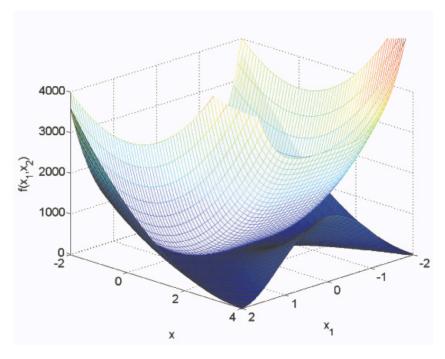

• The second differential $d^2g(x_n|x_n)-d^2f(x_n)$ is PSD.

Remarks

- The MM algorithm and the EM algorithm can be viewed as a vague philosophy for deriving an algorithm
- Examples of the value of a unifying principle and a framework for attacking concrete problems

• The strong connection of the MM algorithm to convexity and inequalities can strengthen skills in these areas

1.2 Majorizing Functions

Recall Jensen's inequality

$$f\left(\sum_{i=1}^n \alpha_i t_i\right) \leq \sum_{i=1}^n \alpha_i f(t_i)$$

for any convex function f(t). Apply it to f of a linear function c^Tx ,

$$f(c^Tx) \leq \sum_i \frac{c_i y_i}{c^Ty} f\left(\frac{c^Ty}{y_i}x_i\right) = g(x|y),$$

provided all components of the vectors c, x and y are positive.

- It reduces optimization over x to a sequence of one-dimensional optimizations over each component x_i .
- An alternative to relax the positivity restrictions:

$$f(c^Tx) \leq \sum_i \alpha_i f\left(\frac{c_i}{\alpha_i}(x_i - y_i) + c^Ty\right) = g(x|y),$$

with $\alpha_i \geq 0, \sum_i \alpha_i = 1$ and $\alpha_i > 0$ whenever $c_i \neq 0.$ For example,

$$\alpha_i = \frac{|c_i|^p}{\sum_j |c_j|^p},$$

for $p \geq 0$.

Linear majorization

$$f(x) \le f(y) + df(y)(x - y) = g(x|y)$$

for any concave function f(x), for example, $\ln(x)$.

Assuming that f(x) is twice differentiable, we look for a matrix B satisfying $B \succeq d^2 f(x)$ and $B \succ 0$. By second-order Taylor exapansion of f(x) at y:

$$\begin{split} f(x) = & f(y) + df(y)(x - y) + \frac{1}{2}(x - y)^T d^2 f(z)(x - y) \\ \leq & f(y) + df(y)(x - y) + \frac{1}{2}(x - y)^T B(x - y) \\ = & g(x|y). \end{split}$$

1.2.1 Example 12.4 Linear Regression

• How MM avoids matrix inversion

1.3 MM Example: t-distribution

• A typical example of 12.5 Elliptically Symmetric Densities

Given iid data w_1, \dots, w_n from multivariate t-distribution $t_p(\mu, \Sigma, \nu)$, the log-likelihood is

$$\begin{split} L(\mu, \Sigma, \nu) &= -\frac{np}{2} \log(\pi \nu) + n \left[\log \Gamma \left(\frac{\nu + p}{2} \right) - \log \Gamma \left(\frac{\nu}{2} \right) \right] - \frac{n}{2} \log \det(\Sigma) \\ &+ \frac{n}{2} (\nu + p) \log \nu - \frac{\nu + p}{2} \sum_{i=1}^{n} \log \left[\nu + (w_j - \mu)^\top \Sigma^{-1} (w_j - \mu) \right]. \end{split}$$

• Since $t \to -\log t$ is a convex function, we can invoke the supporting hyperplane inequality to minorize the terms $-\log[\nu + \delta(w_i, \mu; \Sigma)]$:

$$\begin{split} -\log[\nu + \delta(w_j, \mu; \Sigma)] \geq & -\log[\nu^{(t)} + \delta(w_j, \mu^{(t)}; \Sigma^{(t)})] - \frac{\nu + \delta(w_j, \mu; \Sigma) - \nu^{(t)} - \delta(w_j, \mu^{(t)}; \Sigma^{(t)})}{\nu^{(t)} + \delta(w_j, \mu^{(t)}; \Sigma^{(t)})} \\ = & - \frac{\nu + \delta(w_j, \mu; \Sigma)}{\nu^{(t)} + \delta(w_j, \mu^{(t)}; \Sigma^{(t)})} + c^{(t)}, \end{split}$$

where $c^{(t)}$ is a constant irrelevant to the optimization.

• Minorization function:

$$\begin{split} g(\mu, \Sigma, \nu) &= -\frac{np}{2} \log(\pi \nu) + n \left[\log \Gamma \left(\frac{\nu + p}{2} \right) - \log \Gamma \left(\frac{\nu}{2} \right) \right] - \frac{n}{2} \log \det(\Sigma) \\ &+ \frac{n}{2} (\nu + p) \log \nu - \frac{\nu + p}{2} \sum_{i=1}^{n} \frac{\nu + \delta(w_j, \mu; \Sigma)}{\nu^{(t)} + \delta(w_j, \mu^{(t)}; \Sigma^{(t)})} + c^{(t)}. \end{split}$$

HW NAS Problem 12.15 and 12.16.

1.4 MM Example: non-negative matrix factorization (NNMF)

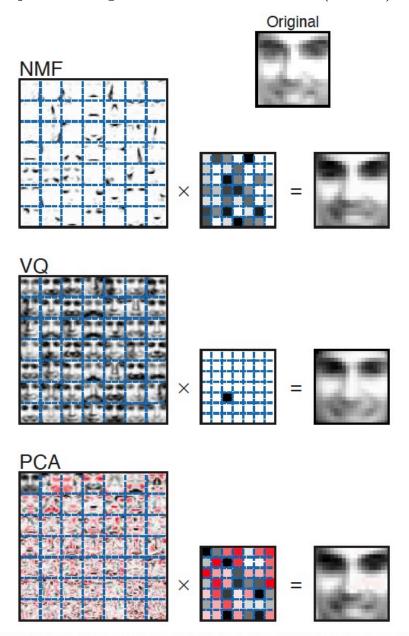

FIGURE 14.33. Non-negative matrix factorization (NMF), vector quantization (VQ, equivalent to k-means clustering) and principal components analysis (PCA) applied to a database of facial images. Details are given in the text. Unlike VQ and PCA, NMF learns to represent faces with a set of basis images resembling parts of faces.

- Nonnegative matrix factorization (NNMF) was introduced by Lee and Seung (1999, 2001) as an analog of principal components and vector quantization with applications in data compression and clustering.
- In mathematical terms, one approximates a data matrix $X \in \mathbb{R}^{m \times n}$ with nonnegative entries x_{ij} by a product of two low-rank matrices $V \in \mathbb{R}^{m \times r}$ and $W \in \mathbb{R}^{r \times n}$ with nonnegative entries v_{ik} and w_{kj} .

• Consider minimization of the squared Frobenius norm

$$L(V,W) = \|X - VW\|_F^2 = \sum_i \sum_j (x_{ij} - \sum_k v_{ik} w_{kj})^2, \quad v_{ik} \geq 0, w_{kj} \geq 0,$$

which should lead to a good factorization.

- L(V, W) is not convex, but bi-convex. The strategy is to alternately update V and W.
- The key is the majorization, via convexity of the function $(x_{ij} x)^2$,

$$(x_{ij} - \sum_k v_{ik} w_{kj})^2 \leq \sum_k \frac{a_{ikj}^{(t)}}{b_{ij}^{(t)}} (x_{ij} - \frac{b_{ij}^{(t)}}{a_{ikj}^{(t)}} v_{ik} w_{kj})^2,$$

where

$$a_{ikj}^{(t)} = v_{ik}^{(t)} w_{kj}^{(t)}, \quad b_{ij}^{(t)} = \sum_{\mathbf{k}} v_{ik}^{(t)} w_{kj}^{(t)}.$$

• This suggests the alternating multiplicative updates

$$\begin{aligned} v_{i,k}^{(t+1)} &\leftarrow v_{i,k}^{(t)} \frac{\sum_{j} x_{i,j} w_{k,j}^{(t)}}{\sum_{j} b_{i,j}^{(t)} w_{k,j}^{(t)}} \\ b_{ij}^{(t+1/2)} &\leftarrow \sum_{k} v_{ik}^{(t+1)} w_{kj}^{(t)} \\ w_{k,j}^{(t+1)} &\leftarrow w_{k,j}^{(t)} \frac{\sum_{i} v_{i,k}^{(t+1)} x_{i,j}}{\sum_{i} v_{i,k}^{(t+1)} b_{i,j}^{(t+1/2)}} \end{aligned}$$

• The update in matrix notation is extremely simple:

$$\begin{split} \mathbf{B}^{(t)} &= \mathbf{V}^{(t)} \mathbf{W}^{(t)} \\ \mathbf{V}^{(t+1)} &= \mathbf{V}^{(t)} \odot \left(\mathbf{X} {\mathbf{W}^{(t)}}^T \right) \oslash \left(\mathbf{B}^{(t)} {\mathbf{W}^{(t)}}^T \right) \\ \mathbf{B}(t + \frac{1}{2}) &= \mathbf{V}^{(t+1)} \mathbf{W}^{(t)} \\ \mathbf{W}^{(t+1)} &= \mathbf{W}^{(t)} \odot \left(\mathbf{X}^T \mathbf{V}^{(t+1)} \right) \oslash \left(\mathbf{B}^{(t + \frac{1}{2})}^T \mathbf{V}(t)^T \right) \end{split}$$

where \odot denotes elementwise multiplication and \oslash denotes elementwise division. If we start with $v_{ik}, w_{kj} > 0$, parameter iterates stay positive.

1.4.1 Python Implementation

```
[9]: # conda install scikit-image
import numpy as np
from PIL import Image
from sklearn.decomposition import NMF
from skimage import data
```

```
[10]: img = data.astronaut()
img.shape
```

[10]: (512, 512, 3)

[11]: img_show = Image.fromarray(img)
img_show

[11]:

```
[12]: img = img_show.convert('L')
img_array = np.array(img)
img_array.shape
```

[12]: (512, 512)

```
[13]: # Perform non-negative matrix factorization
      model = NMF(n_components=50, init='random', random_state=0)
      W = model.fit_transform(img_array)
      H = model.components_

     (50, 512)
[15]: # Reconstruct image from compressed data
      compressed_img = np.dot(W, H)
      compressed_img = np.clip(compressed_img, 0, 255).astype(np.uint8)
      # Convert image back to PIL format and save
      compressed_img = Image.fromarray(compressed_img.reshape(img.size))
      compressed_img
```

[15]:

[16]: compressed_img.save('compressed_astronaut.jpg')

1.5 MM example: Netflix and matrix completion

Netflix database consists of about $m \approx 10^6$ users and about $n \approx 25,000$ movies. Users rate movies; the ratings are recorded into matrix $A \in R^{m \times n}$. Only 1% (over 100 million) of the ratings are observed.

	The Code and the C	Ronry-Busy	MATRIX	A REALINED	WHIPLASH	•••
Alice	1			4		
Bob		2	5			
Carol			4	5		
Dave	5				4	
:						

- Netflix challenge: impute the unobserved ratings for personalized recommendation. (http://en.wikipedia.org/wiki/Netflix_Prize)
- $\Omega = \{(i,j) : \text{observed entries}\}\$ index the set of observed entries and $P_{\Omega}(\mathbf{M})$ denote the projection of matrix \mathbf{M} to Ω . The problem

$$\min_{\mathrm{rank}(\mathbf{X}) \leq r} \frac{1}{2} \left\| P_{\Omega}(\mathbf{Y}) - P_{\Omega}(\mathbf{X}) \right\|_F^2 = \frac{1}{2} \sum_{(i,j) \in \Omega} (y_{ij} - x_{ij})^2$$

is non-convex and hard.

• Convex relaxation of the rank minimization problem is:

$$\min_{\mathbf{X}} f(\mathbf{X}) = \frac{1}{2} \|\mathbf{P}_{\Omega}(\mathbf{Y}) - \mathbf{P}_{\Omega}(\mathbf{X})\|_F^2 + \lambda \|\mathbf{X}\|_*,$$

where $\|\mathbf{X}\|_* = \|\sigma(\mathbf{X})\|_1 = \sum_i \sigma_i(\mathbf{X})$ is the nuclear norm.

• Majorization step:

$$\begin{split} f(\mathbf{X}) = & \frac{1}{2} \sum_{(i,j) \in \Omega} (y_{ij} - x_{ij})^2 + \frac{1}{2} \sum_{(i,j) \notin \Omega} 0 + \lambda \|\mathbf{X}\|_* \\ \leq & \frac{1}{2} \sum_{(i,j) \in \Omega} (y_{ij} - x_{ij})^2 + \frac{1}{2} \sum_{(i,j) \notin \Omega} (x_{ij}^{(t)} - x_{ij})^2 + \lambda \|\mathbf{X}\|_* \\ = & \frac{1}{2} \|\mathbf{X} - \mathbf{Z}^{(t)}\|_F^2 + \lambda \|\mathbf{X}\|_* \\ = & g(\mathbf{X}|\mathbf{X}^{(t)}), \end{split}$$

where $\mathbf{Z}^{(t)} = \mathbf{P}_{\Omega}(\mathbf{Y}) + \mathbf{P}_{\Omega^{\perp}}(\mathbf{X}^{(t)})$. (Fill in missing entries by the current imputation)

• Minimization step: Rewrite the surrogate function

$$g(\mathbf{X}|\mathbf{X}^{(t)}) = \frac{1}{2}\|\mathbf{X}\|_F^2 - \operatorname{tr}(\mathbf{X}^T\mathbf{Z}^{(t)}) + \frac{1}{2}\|\mathbf{Z}^{(t)}\|_F^2 + \lambda\|\mathbf{X}\|_*$$

Let σ_i be the (ordered) sigular values of \mathbf{X} and ω_i be the (ordered) sigular values of $\mathbf{Z}^{(t)}$. Observe

$$\|\mathbf{X}\|_F^2 = \sum_i \sigma_i^2 \|\mathbf{Z}^{(t)}\|_F^2 = \sum_i \omega_i^2$$

and by von Neumann's inequality,

$$\operatorname{tr}(\mathbf{X}^T\mathbf{Z}^{(t)}) \leq \sum_i \sigma_i \omega_i$$

with equality achieved if and only if the left and right singular vectors of the two matrices coincide. Therefore we should choose \mathbf{X} with the same singular vectors as $\mathbf{Z}^{(t)}$ and

$$\begin{split} g(\mathbf{X}|\mathbf{X}^{(t)}) = &\frac{1}{2} \sum_{i} \sigma_{i}^{2} - \sum_{i} \sigma_{i} \omega_{i} + \frac{1}{2} \sum_{i} \omega_{i}^{2} + \lambda \sum_{i} \sigma_{i} \\ = &\frac{1}{2} \sum_{i} (\sigma_{i} - \omega_{i})^{2} + \lambda \sum_{i} \sigma_{i}, \end{split}$$

with minimizer as

$$\sigma_i^{(t+1)} = \max(0, \omega_i - \lambda) = (\omega_i - \lambda)_+.$$

- Algorithm for matrix completion:
 - Initialize $\mathbf{X}^{(0)} \in \mathbb{R}^{m \times n}$
 - Repeat
 - $* \ \mathbf{Z}^{(t)} \leftarrow \mathcal{P}_{\Omega}(\mathbf{Y}) + \mathcal{P}_{\Omega^{\perp}}(\mathbf{X}^{(t)})$
 - * Compute SVD: Udiag(w)V $^{\top} \leftarrow \mathbf{Z}(t)$
 - * $\mathbf{X}^{(t+1)} \leftarrow \mathbf{U} \operatorname{diag}[(\mathbf{w} \lambda)_{+}] \mathbf{V}^{\top}$
 - objective value converges

[]:
